# **Data Structure and Algorithms – Tree**

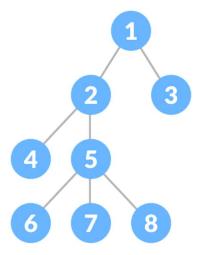

Tree represents the nodes connected by edges.

#### **Definition**

In computer science, a **tree** is a widely used abstract data type that simulates a hierarchical tree structure, with a root value and subtrees of children with a parent node, represented as a set of linked nodes.

- A tree data structure can be defined recursively as a collection of nodes (starting at a root node), where each node is a data structure consisting of a value, together with a list of references to nodes (the "children"), with the constraints that no reference is duplicated, and none points to the root.
- Alternatively, a tree can be defined abstractly as a whole (globally) as an ordered tree, with a value assigned to each node.
- Both these perspectives are useful: while a tree can be analyzed mathematically as a whole, when actually represented as a data structure it is usually represented and worked with separately by node (rather than as a set of nodes and an adjacency list of edges between nodes, as one may represent a digraph, for instance).
- For example, looking at a tree as a whole, one can talk about "the parent node" of a given node, but in general, as a data structure, a given node only contains the list of its children but does not contain a reference to its parent (if any).

A tree is a nonlinear hierarchical data structure that consists of nodes connected by edges.

A Tree

### Why Tree Data Structure?

- Other data structures such as arrays, linked list, stack, and queue are linear data structures that store data sequentially.
- In order to perform any operation in a linear data structure, the time complexity increases with the increase in the data size.
- But, it is not acceptable in today's computational world.

Different tree data structures allow quicker and easier access to the data as it is a non-linear data structure.

### **Tree Terminologies**

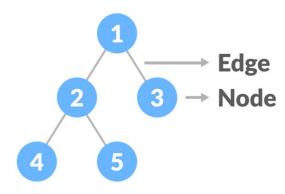

#### Node

- A node is an entity that contains a key or value and pointers to its child nodes.
- The last nodes of each path are called leaf nodes or external nodes that do not contain a link/pointer to child nodes.

 The node having at least a child node is called an internal node.

# Edge

It is the link between any two nodes.

## Nodes and edges of a tree

#### **Root**

It is the topmost node of a tree.

# **Height of a Node**

The height of a node is the number of edges from the node to the deepest leaf (ie. the longest path from the node to a leaf node).

## **Depth of a Node**

The depth of a node is the number of edges from the root to the node.

### **Height of a Tree**

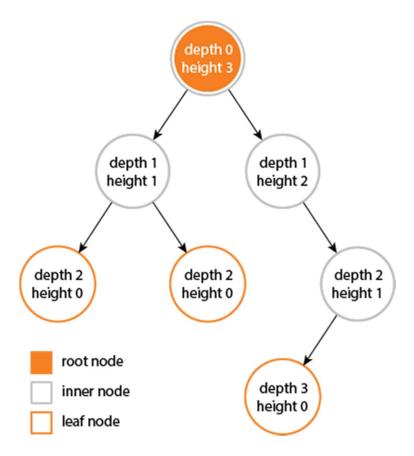

The height of a Tree is the height of the root node or the depth of the deepest node.

### The depth and height are properties of a *node*:

- The **depth** of a node is the number of edges from the node to the tree's root node.
- A root node will have a depth of 0.
- The height of a node is the number of edges on the longest path from the node to a leaf.
- A leaf node will have a height of 0.

### Properties of a tree:

- The height of a tree would be the height of its root node, or equivalently, the depth of its deepest node.
- The **diameter** (or **width**) of a tree is the number of *nodes* on the longest path between any two leaf nodes. The tree below has a diameter of 6 nodes.

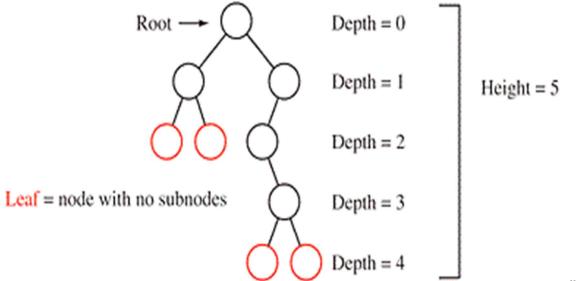

# It means height == max depth

- 6
- The Height (or depth) of a tree is defined to be the maximum level of any node in the tree. Some authors define depth of a node to be the length of the longest path from the root node to that node, which yields the relation:
- Depth of the tree = Height of the tree 1

### Depth:

1. Tree: Number of edges/arc f

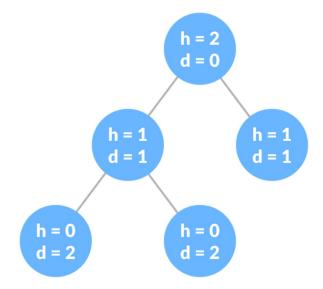

rom

the root node to the leaf node of the tree is called as the Depth of the Tree.

- 2. **Node**: **Number of edges/arc** from the root node to that node is called as the Depth of that node.
  - Another example:

.

- Another way to understand those concept is as follow:
- Depth: Draw a horizontal line at the root position and treat this line as ground. So the depth of the root is 0, and all its children are grow downward so each level of nodes has the current depth + 1.
- Height: Same horizontal line but this time the ground position is external nodes, which is the leaf of tree and count upward.

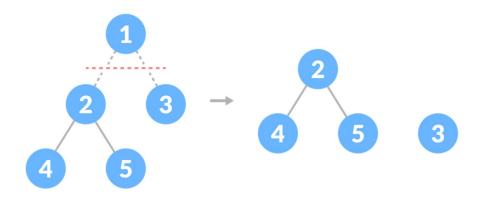

# Height and depth of each node in a tree

# **Degree of a Node**

The degree of a node is the total number of branches of that node.

#### **Forest**

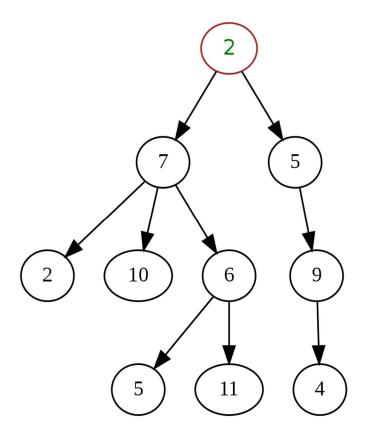

A collection of disjoint trees is called a forest.

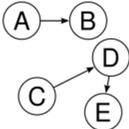

**Creating forest** 

### from a tree

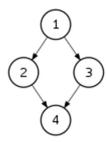

You can create a forest by cutting the root of a tree.

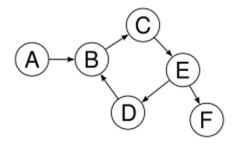

# **Preliminary definition**

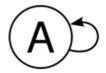

**Not a tree:** two non-<u>connected</u> parts,  $A \rightarrow B$  and  $C \rightarrow D \rightarrow E$ . There is more than one root.

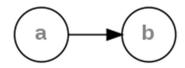

**Not a tree:** undirected cycle 1-2-4-3. 4 has more than one parent (inbound edge).

Not a tree: cycle  $B \rightarrow C \rightarrow E \rightarrow D \rightarrow B$ . B has more than one parent (inbound edge).

**Not a tree:** cycle  $A \rightarrow A$ . A is the root but it also has a parent.

# Each linear list is trivially a tree

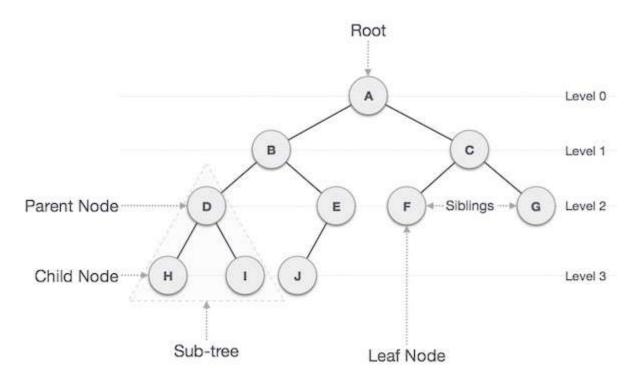

- A tree is a nonlinear data structure, compared to arrays, linked lists, stacks and queues which are linear data structures.
- A tree can be empty with no nodes or a tree is a structure consisting of one node called the root and zero or one or more subtrees.

#### Common uses

- Representing hierarchical data such as:
  - Abstract syntax trees for computer languages
  - Parse trees for human languages
  - Document Object Models of XML and HTML documents
  - JSON and YAML documents being processed
- Search trees store data in a way that makes an efficient search algorithm possible via tree traversal
  - A binary search tree is a type of binary tree
- Representing sorted lists of data
- As a workflow for compositing digital images for visual effects
- Storing Barnes-Hut trees used to simulate galaxies

We will discuss binary tree or binary search tree specifically.

- Binary Tree is a special data structure used for data storage purposes.
- A binary tree has a special condition that each node can have a maximum of two children.
- A binary tree has the benefits of both an ordered array and a linked list as search is as quick as in a sorted array and insertion or deletion operation are as fast as in linked list.

### **Important Terms**

Following are the important terms with respect to tree.

- Path Path refers to the sequence of nodes along the edges of a tree.
- Root The node at the top of the tree is called root. There is only one root per tree and one path from the root node to any node.
- Parent Any node except the root node has one edge upward to a node called parent.
- **Child** The node below a given node connected by its edge downward is called its child node.
- Leaf The node which does not have any child node is called the leaf node.
- Subtree Subtree represents the descendants of a node.
- Visiting Visiting refers to checking the value of a node when control is on the node.
- Traversing Traversing means passing through nodes in a specific order.

- **Levels** Level of a node represents the generation of a node. If the root node is at level 0, then its next child node is at level 1, its grandchild is at level 2, and so on.
- keys Key represents a value of a node based on which a search operation is to be carried out for a node.

### **Terminology**

- A <u>node</u> is a structure which may contain a value or condition, or represent a separate data structure (which could be a tree of its own).
- Each node in a tree has zero or more **child nodes**, which are below it in the tree (by convention, trees are drawn growing downwards).
- A node that has a child is called the child's parent node (or superior).
- A node has at most one parent, but possibly many *ancestor* nodes, such as the parent's parent. Child nodes with the same parent are **sibling nodes**.
- An internal node (also known as an inner node, inode for short, or branch node) is any node of a tree that has child nodes.
- Similarly, an external node (also known as an outer node, leaf node, or terminal node) is any node that does not have child nodes.
- The topmost node in a tree is called the **root node**.
   Depending on the definition, a tree may be required to have a root node (in which case all trees are non-empty), or may be allowed to be empty, in which case it does not necessarily have a root node.
- Being the topmost node, the root node will not have a parent.
- It is the node at which algorithms on the tree begin, since as a data structure, one can only pass from parents to children.
- Note that some algorithms (such as post-order depth-first search) begin at the root, but first visit leaf nodes (access the

value of leaf nodes), only visit the root last (i.e., they first access the children of the root, but only access the value of the root last).

- All other nodes can be reached from it by following edges or links.
- (In the formal definition, each such path is also unique.)
- In diagrams, the root node is conventionally drawn at the top.
   In some trees, such as <a href="heaps">heaps</a>, the root node has special properties. Every node in a tree can be seen as the root node of the subtree rooted at that node.
- The **height** of a node is the length of the longest downward path to a leaf from that node.
- The height of the root is the height of the tree.
- The **depth** of a node is the length of the path to its root (i.e., its *root path*).
- This is commonly needed in the manipulation of the various self-balancing trees, <u>AVL Trees</u> in particular.
- The root node has depth zero, leaf nodes have height zero, and a tree with only a single node (hence both a root and leaf) has depth and height zero. Conventionally, an empty tree (tree with no nodes, if such are allowed) has height −1.
- A **subtree** of a tree *T* is a tree consisting of a node in *T* and all of its descendants in *T*.
- Nodes thus correspond to subtrees (each node corresponds to the subtree of itself and all its descendants) – the subtree corresponding to the root node is the entire tree, and each node is the root node of the subtree it determines; the subtree corresponding to any other node is called a proper subtree (by analogy to a proper subset).

### Other terms used with trees:

### Neighbor

Parent or child.

#### **Ancestor**

A node reachable by repeated proceeding from child to parent.

#### Descendant

A node reachable by repeated proceeding from parent to child. Also known as *subchild*.

#### Branch node

#### Internal node

A node with at least one child.

### Degree

For a given node, its number of children. A leaf has necessarily degree zero.

## Degree of tree

The degree of a tree is the maximum degree of a node in the tree.

#### **Distance**

The number of edges along the shortest path between two nodes.

#### Level

1 + the number of edges between a node and the root, i.e. (depth + 1)

### Width

The number of nodes in a level.

### Breadth

The number of leaves.

#### **Forest**

A set of  $n \ge 0$  disjoint trees.

#### Ordered tree

A rooted tree in which an ordering is specified for the children of each vertex.

#### Size of a tree

Number of nodes in the tree.

### **Degree of a Tree**

- Degree of a node is related to the degree of a tree.
- The **degree** of a **tree** is the maximum **degree** of a node in the **tree**. For example:
- If the maximum degree of a node is 2, then it is a binary tree. Likewise, if the maximum degree of a node is 3, then it becomes a ternary tree.
- The degree of a node is the number of edges for which it is one of the endpoints.
- The degree of a tree (or any graph, for that matter) is the maximum degree over all of the nodes in the graph.

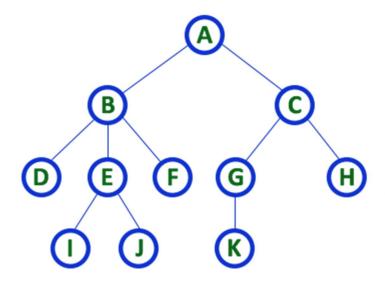

•

P.S: Degree of a node is the maximum number of child nodes it can have.

### **Supplementary materials:**

- In linear data structure data is organized in sequential order and in non-linear data structure data is organized in random order.
- A tree is a very popular non-linear data structure used in a wide range of applications.
- A tree data structure can be defined as follows...
- Tree is a non-linear data structure which organizes data in hierarchical structure and this is a recursive definition.
- A tree data structure can also be defined as follows...
- Tree data structure is a collection of data (Node) which is organized in hierarchical structure recursively
- In tree data structure, every individual element is called as Node.
- Node in a tree data structure stores the actual data of that particular element and link to next element in hierarchical structure.
- In a tree data structure, if we have N number of nodes then we can have a maximum of N-1 number of links.

# **Example**

### TREE with 11 nodes and 10 edges

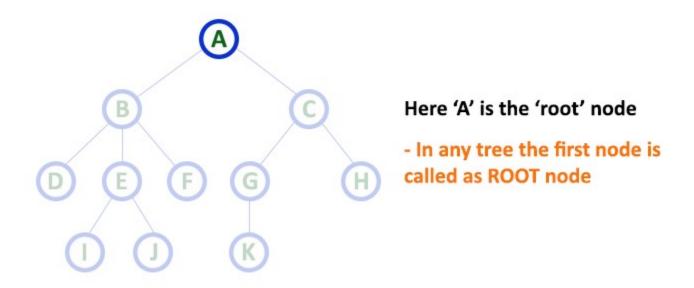

- In any tree with 'N' nodes there will be maximum of 'N-1' edges
- In a tree every individual element is called as 'NODE'

# **Terminology**

In a tree data structure, we use the following terminology...

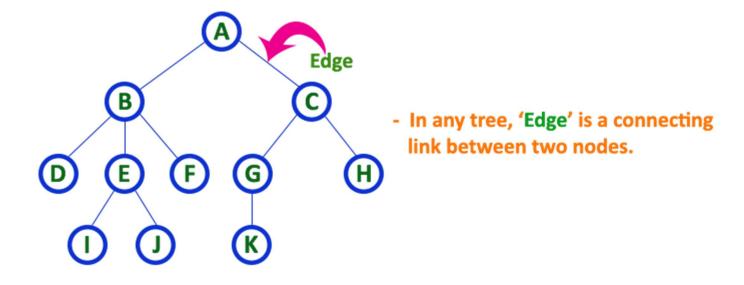

#### 1. Root

In a tree data structure, the first node is called as **Root Node**. Every tree must have a root node. We can say that the root node is the origin of the tree data structure. In any tree, there must be only one root node. We never have multiple root nodes in a tree.

### 2. Edge

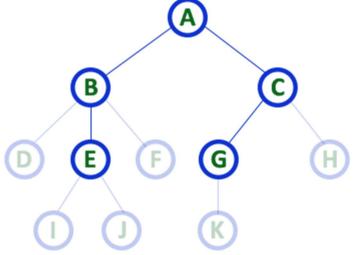

In a tree data structure, the connecting link between any two nodes is called as **EDGE**. In a tree with 'N' number of nodes there will be a maximum of 'N-1' number of edges.

### 3. Parent

In a tree data structure, the node which is a predecessor of any node is called as **PARENT NODE**.

In simple words, the node which has a branch from it to any other node is called a parent node. Parent node can also be defined as "The node which has child / children".

# Here A, B, C, E & G are Parent nodes

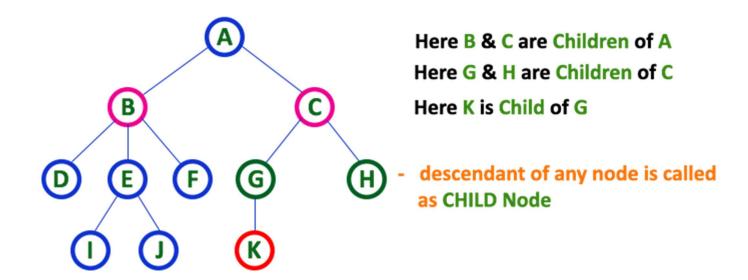

- In any tree the node which has child / children is called 'Parent'
- A node which is predecessor of any other node is called 'Parent'

#### 4. Child

In a tree data structure, the node which is descendant of any node is called as **CHILD Node**.

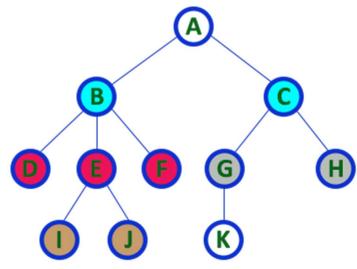

In simple words, the node which has a link from its parent node is called as child node.

In a tree, any parent node can have any number of child nodes. In a tree, all the nodes except root are child nodes.

### 5. Siblings

In a tree data structure, nodes which belong to same Parent are called as **SIBLINGS**. In simple words, the nodes with the same parent are called Sibling nodes.

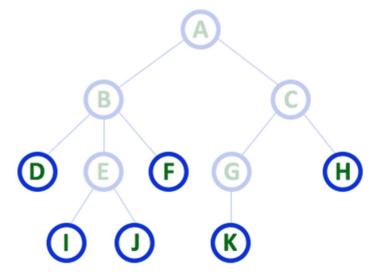

Here B & C are Siblings
Here D E & F are Siblings
Here G & H are Siblings
Here I & J are Siblings

- In any tree the nodes which has same Parent are called 'Siblings'
- The children of a Parent are called 'Siblings'

#### 6. Leaf

In a tree data structure, the node which does not have a child is called as **LEAF Node**. In simple words, a leaf is a node with no child.

In a tree data structure, the leaf nodes are also called as **External Nodes**. External node is also a node with no child. In a tree, <u>leaf node is also called as 'Terminal' node</u>.

### Here D, I, J, F, K & H are Leaf nodes

- In any tree the node which does not have children is called 'Leaf'
- A node without successors is called a 'leaf' node

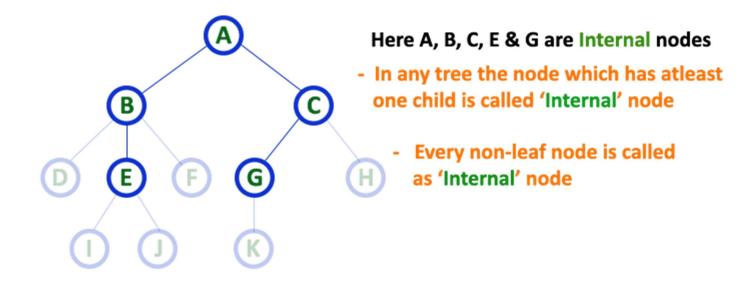

#### 7. Internal Nodes

In a tree data structure, the node which has at least one child is called as **INTERNAL Node**. In simple words, an internal node is a node with at least one child.

In a tree data structure, nodes other than leaf nodes are called as **Internal Nodes**.

The root node is also said to be Internal Node if the tree has more than one node.

Internal nodes are also called as 'Non-Terminal' nodes.

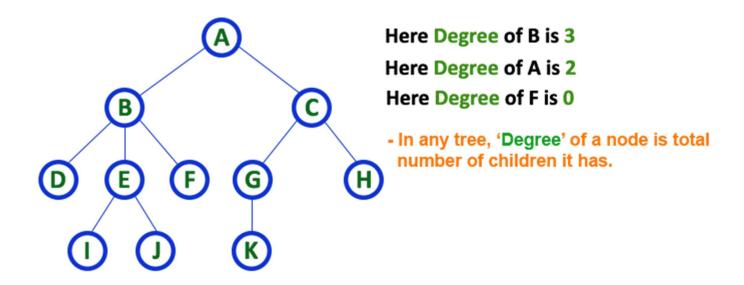

### 8. Degree

In a tree data structure, the total number of children of a node is called as **DEGREE** of that Node.

In simple words, the Degree of a node is total number of children it has.

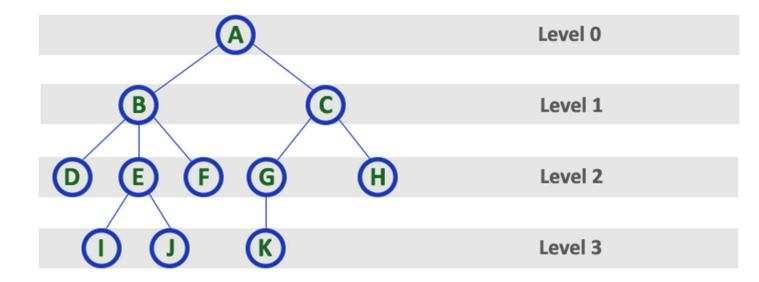

The highest degree of a node among all the nodes in a tree is called as 'Degree of Tree'

### 9. Level

In a tree data structure, the root node is said to be at Level 0 and the children of root node are at Level 1 and the children of the nodes which are at Level 1 will be at Level 2 and so on...

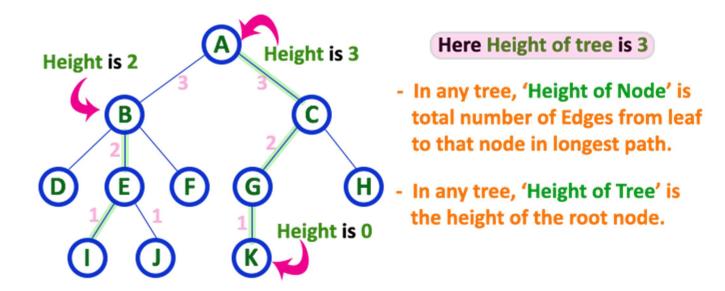

In simple words, in a tree each step from top to bottom is called as a Level and the Level count starts with '0' and incremented by one at each level (Step).

### 10. Height

In a tree data structure, the total number of edges from leaf node to a particular node in the longest path is called as **HEIGHT** of that Node.

In a tree, height of the root node is said to be height of the tree. In a tree, height of all leaf nodes is '0'.

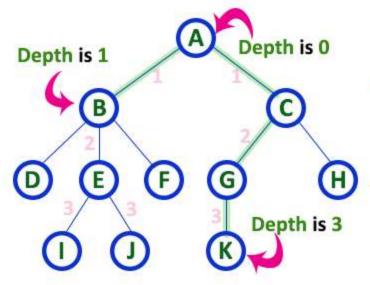

### 11. Depth

In a tree data structure, the total number of edges from root node to a particular node is called as **DEPTH** of that Node.

In a tree, the total number of edges from root node to a leaf node in the longest path is said to be **Depth of the tree**.

In simple words, the highest depth of any leaf node in a tree is said to be depth of that tree. In a tree, **depth of the root node is '0'.** 

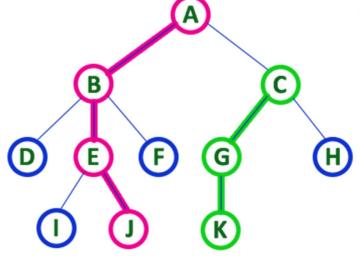

### Here Depth of tree is 3

- In any tree, 'Depth of Node' is total number of Edges from root to that node.
- In any tree, 'Depth of Tree' is total number of edges from root to leaf in the longest path.

#### 12. Path

In a tree data structure, the sequence of Nodes and Edges from one node to another node is called as **PATH** between that two Nodes. **Length of a Path** is total number of nodes in that path.

In below example the path A - B - E - J has length 4.

 In any tree, 'Path' is a sequence of nodes and edges between two nodes.

Here, 'Path' between A & J is

A - B - E - J

Here, 'Path' between C & K is C - G - K

# 13. Sub Tree

In a tree data structure, each child from a node forms a subtree recursively. Every child node will form a subtree on its parent node.
